Lattice 2001 : Reflections

all my apologies are in this title

P. Hasenfratz
Bern

1. $K \to \pi\pi$ from $K \to \pi$ & $K \to 0$ with domain-wall fermions

CP-PACS
RBC

plenary: Martinelli

It is exciting and frightening to see how brains, software and hardware come together in a highly relevant project and push it to the end, which does not necessarily mean full success.

2. Chiral symmetric fermions

plenaries: Kikukawa, Hernandez

went through a rapid development during the last years

3. Selected topics

topological susceptibility

an algorithm

cut-off effects

1. $K \to \pi\pi$ from $K \to \pi$ & $K \to 0$ from DWF

CP-PACS (Noaki)
RBC (Mawhinney, Cristian, Bloom)

relevant physics
active field of current research
complex problem with relations to exciting theoretical methods
central problem in this community since the early days of lattice computations

* * *

$K \to \pi\pi$ exhibits two significant phenomena

$$\frac{\Gamma(K_S \to \pi^+\pi^-)}{\Gamma(K^+ \to \pi^+\pi^0)} \sim 450$$

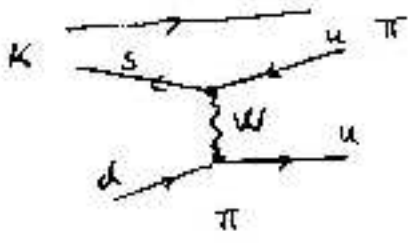
$\Delta I = 1/2$ (γ $3/2$)
$\Delta I = 3/2$

and (direct) CP violation

non-trivial interplay of strong & electroweak forces

several energy scales $m_t, \ldots, m_u, m_d$

(a) OPE



dressed with QCD interactions

the 4-fermion interaction is almost pointlike

factorization $A = C(\mu/M_W, \alpha_s) \cdot \langle \mathcal{O} \rangle + O(\mu^2/M$

if $\mu \gg \Lambda_{QCD}$ expect: $C(\mu/M_W, \alpha_s)$ can be calculated in PT

if the charm quark is not simulated : $\mu \leq 1.3$ GeV

given $\mu/\Lambda_{\overline{MS}}$) is PT applicable?

an important technical issue

one can check consistency within PT itself,

or preferably compare with the full NP result

a) physical quantities with high energy scales

short distance part of the potential
small volume, high temperature physics, ...

b) finite and divergent renormalization constants

Z

c) cut-off effects

a) very few tests

q-$\bar{q}$ potential/force

$0.05\ \text{fm} \leq r \leq 0.8\ \text{fm}$

$\Lambda_{\overline{MS}}$ is known (quenched)

→ PT for the force is a parameter free prediction (3 loop)

TABLE VII: Final results for improvement and renormalization constants. The first error is statistical, and the second, where present, corresponds to the difference between using 2-point and 3-point discretization of the derivative used in the extraction of c_A.

bosonic string model $F(r) = \sigma - \frac{\pi}{12 r^2}$

(PT) works – within the errors – for $r \lesssim 0.15$ fm ~ 1.3 GeV

?!

Kuti (parallel talk)

Kuti, Juge, Morningstar

b) Z factors

PT is poor

quenched QCD, $\mu = 2$ GeV

Z_P:

fermion type	1-loop	NP
Wilson Gimenez et al	0.62	0.45
clover (NP) Becirevic et al.	0.59	0.39
staggered Aoki et al.	0.54	0.34

c) improvement coeff.s

scale $\sim \frac{1}{a} \sim 2$-3 GeV

PT is not reliable

analogies between Symanzik pr. & OPE

Bhattacharya et al. * * * however: a, b, c form 3 different types for PT !

The "tree graph" above generates 2 operators

$$Q_1 = (\bar{s}_a u_b)_L (\bar{u}_b d_a)_L$$
$$Q_2 = a\ a\ \ b\ b \leftarrow \text{color}$$
$$\Big\} (8_L, 1_R) \oplus (27_L, 1_R)$$

$$(\bar{s}u)_L = \bar{s}\gamma^\mu(1-\gamma_5)u$$

$$\langle \pi\pi^I | Q_i | K \rangle \qquad i = 1,2 \qquad I = 0,2$$

the sum over i, weighted with the Wilson coeffs $z_i(\mu)$

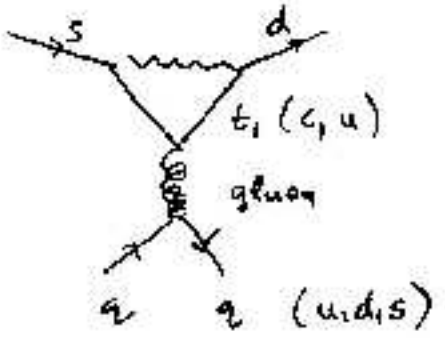
should ~ explain $\omega = \dfrac{\mathrm{Re}\,A_0}{\mathrm{Re}\,A_2} \sim 22$ $\qquad K \to \pi\pi^I = A_I e^{i\delta}$

* * *

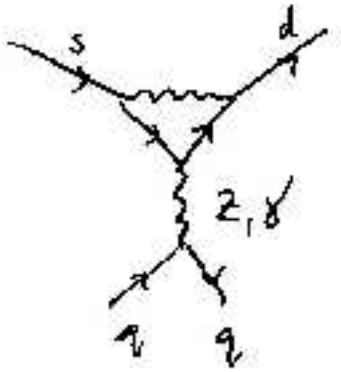
"tree graph" does not know about the 3rd generation

we have to go beyond the leading appr.

CP conserving



QCD penguin



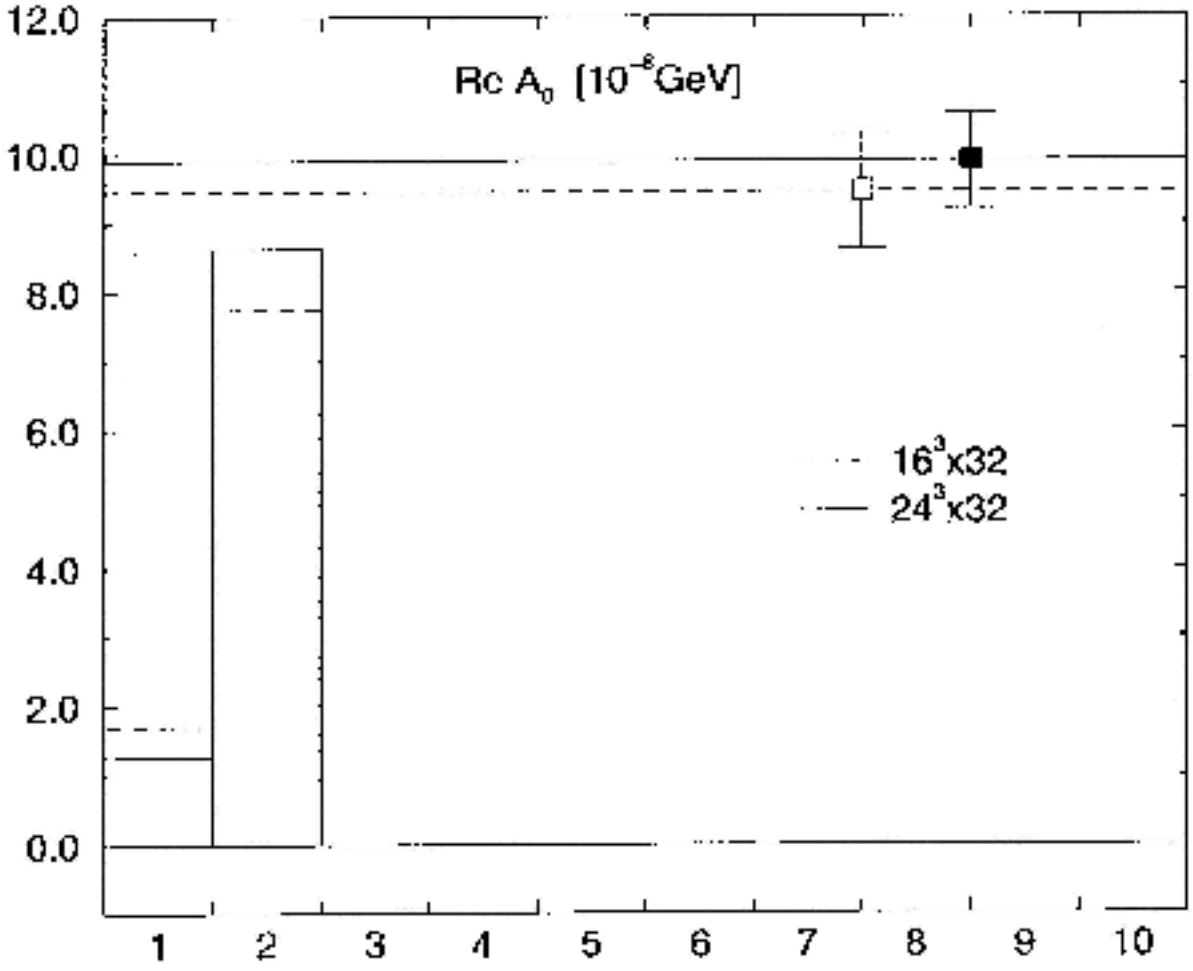
electroweak penguin

z_i, y_i : Munich, Rome group

$$\mathrm{Im}\,A_I = -\,\mathrm{Im}\left(V_{ts}^* V_{td}\right) \frac{G_F}{\sqrt{2}} \sum_{i=3}^{10} y_i(\mu) \langle Q_i \rangle_I$$

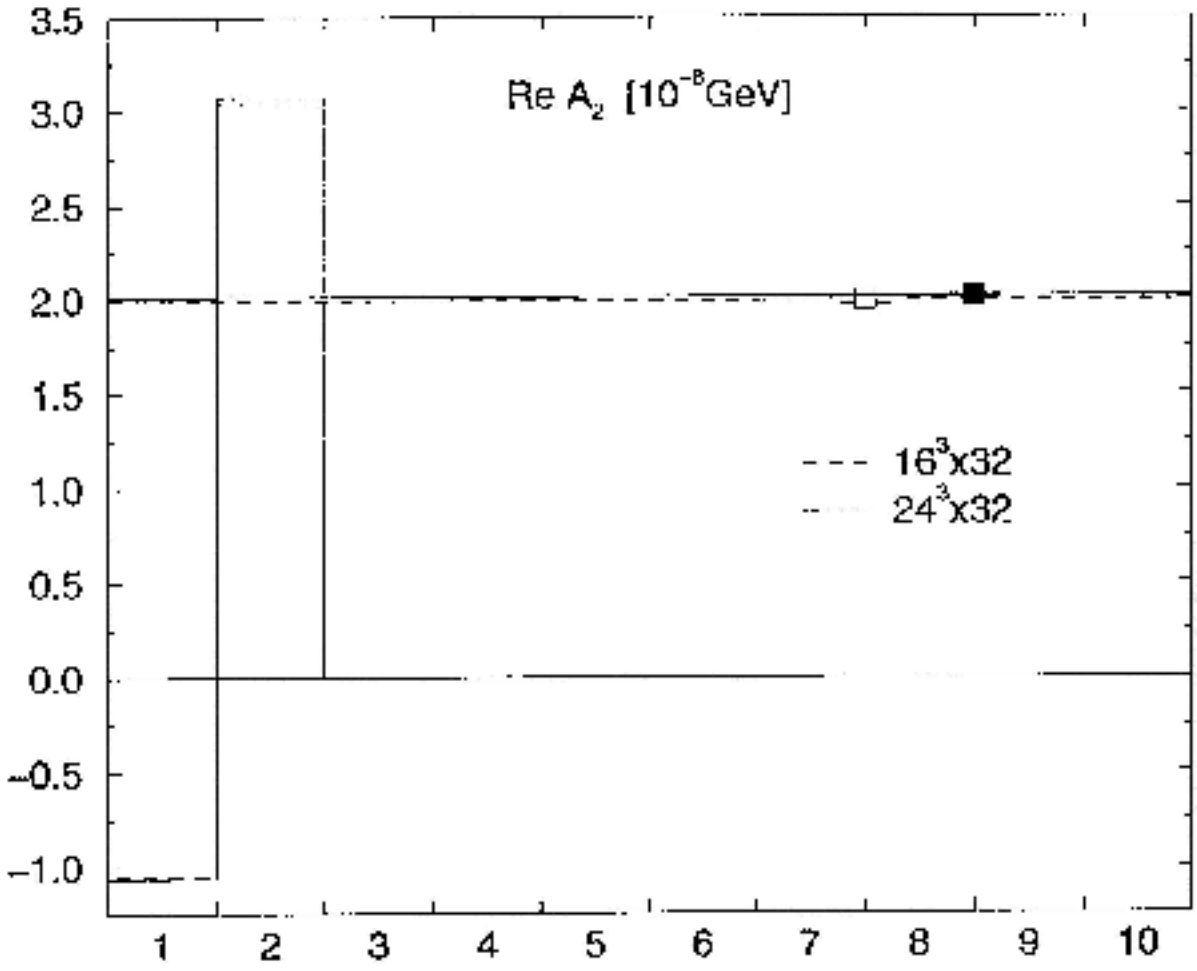
Re A_0 is dominated by Q_1, Q_2

CP-PACS



Re A_2 is dominated by Q_1, Q_2

CP-PACS



it is expected (factorization arguments) that

$\langle Q_6 \rangle_0$ & $\langle Q_8 \rangle_2$ dominate (confirmed by the results)

$$\varepsilon'/\varepsilon \simeq \omega \frac{G_F}{2|\varepsilon| \, \mathrm{Re}A_0} \mathrm{Im}(V_{ts}^* V_{td}) \left(y_6 \langle Q_6 \rangle_0 - \omega y_8 \langle Q_8 \rangle \right)$$

potential cancellation

$(8_L, 1_R)$ $\quad Q_6 = (\bar{s}d)_L (\bar{q}q)_R$ $\quad$ QCD penguin

$(8_L, 8_R)$ $\quad Q_8 = \frac{1}{2} (\bar{s}d)_L \left(2(\bar{u}u)_R - (\bar{d}d)_R - (\bar{s}s)_R \right)$ $\quad$ electroweak penguin

CP-PACS $\Delta I = 3/2$ amplitude $(\mathrm{Re}A_2)$: $\sim$ exp.

$\Delta I = 1/2$: a factor of 2 smaller

ϵ'/ϵ : is negative, small $\sim 10^{-4}$

RBC $\mathrm{Re}A_0$, $\mathrm{Re}A_2$, $\mathrm{Re}A_0/\mathrm{Re}A_2$: $\sim$ exp

ϵ'/ϵ : is negative, small

... tour de force ...

large chiral corrections?

quenching?

missing final state int.s?

Golterman-Pallante?

- the whole reduction is on the <u>tree level</u>

  on the p^4 level the low energy constants in $K \to \pi\pi$ can not be determined from $K \to \pi$, $K \to 0$

- $O(p^4)$ (P)(Q) χPT can be used to fit $K \to \pi$, $K \to 0$

  but $K \to \pi\pi$ remains on tree level

- the $O(p^4)$ corrections are estimated to be significant

  ($M_K \sim 500$ MeV) Golterman, Pallante

- with the "reduction" the $\pi - \pi$ final state int. is lost

  an uncontrolled approximation? plenary : Colangelo

- the "reduction" relies heavily on chiral symm.

  with Wilson fermion $\Delta I = 1/2$ sector beyond reach

- can the power div. subtraction be numerically controlled? (repeatedly discussed at this conference)

  it seems so

- chiral Behaviour?

  after subtraction all the matrixelements should go to zero in the chiral limit

  $$\langle \quad \rangle = a_0 + a_1 M^2 + \cdots$$

  a_0 should be 0 ↑ this is what we need

2. Chiral symmetric fermions

plenary { Kikukawa, Hernandez } { Damgaard, Edwards }

Ginsparg - Wilson (GW) relation (1982)

"mildest way" to break chiral symmetry

$$\gamma_5 D + D\gamma_5 = D\gamma_5 D \qquad * \qquad D = D(U)$$

or equivalently $D^{ab}_{\alpha\beta}(x,x')$

$$\gamma_5 D^{-1}(x,x') + D^{-1}(x,x')\gamma_5 = \gamma_5 \delta_{xx'} \qquad * *$$

the GW relation was not derived

it was guessed from what was found in a free field theory

** indicates that D will respect physical chiral symmetry

* is a non-linear equation

$\not\exists$ ultralocal solution — Horvath, Berkenbusch

D has a tail

the solution D should be local, however

$$D(x,x') \underset{|x-x'|\gg 1}{\sim} e^{-M(a|x-x'|)}, \quad M \sim \Lambda^{cut}$$

on "locality of the action in a QFT"

↓

universality

↓

predictive power

based on intuition

collective motion of a large # of degrees of freedom

the microscopic details forgotten

if, however, the direct couplings in the action (hand made!) compete with this collective motion, the model is good for nothing.

We are ready to give up – for a period – unitarity (quenching), but we do not give up predictive power.

For this reason the careful checks concerning the locality of GW Dirac operators are very important.

Hernandez, Jansen, Lüscher

↑ ?

absolute size of baryon number violation?

Suzuki:

real repr. Weyl fermions

↓ equivalent to

Majorana fermions (L-R symm.)

on the lattice

based on this observation suggested a

"natural choice" for # for Weyl fermions

in complex repr.

this paper influences an interesting problem

$$\psi_L = \hat{P}_L \psi \qquad \hat{P}_L = \frac{1}{2}(1-\hat{\gamma}_5)$$

$$\bar{\psi}_L = \bar{\psi} P_R \qquad P_R = \frac{1}{2}(1+\gamma_5)$$

asymmetric

$$\bar{\psi}_L D \psi_L \xrightarrow[CP]{} \bar{\psi}_L D \psi_L - \frac{1}{2} \bar{\psi} D \gamma_5 D \psi \Big|_{\{U\}\to\{U^{CP}\}}$$

on that level CP is violated, unlike in the "cont."

one can introduce a cont. parameter in $\hat{P}_L$, P_R

but CP violation remains, or locality is violated

as a consequence

$$\left| \det D_L(U^{CP})_{\not k} \right| = \left(\frac{2}{a}\right)^{-Q(U)} \left| \det D_L(U)_{\not k} \right|$$

↑ zero modes are taken out

↑ violates CP ?

Suzuki's suggested factor would just eliminate this.

Is this suggestion consistent with clustering?
